 - In this work, I select red clump stars from the ~ 200 million stars which have photometry from 2MASS, AllWISE, *Gaia*, and Pan-STARRS. I do this by inferring the effective temperature, surface gravity, and the asteroseismic parameters (period spacing and frequency separation) using a Mixture Density network. The final result is a sample of ~ 4.3 million red clump stars with a contamination rate of $\sim 35\%$. This is the largest and most distant sample of red clump stars with $> 280,000$ stars at distances > 10 kpc.

 - This paper is the first part of the Chemical Origins of Metal-poor Bulge Stars (COMBS) survey that will chemo-dynamically characterize the metal-poor bulge population. In this work, I determined the stellar parameters of 26 stars and their elemental abundances for 22 elements using $R \sim 47,000$ VLT/UVES spectra and contrast their elemental properties with that of other Galactic stellar populations. I found that the elemental abundances we derive for our metal-poor bulge stars have lower overall scatter than typically found in the halo. This indicates that these stars may be a distinct bulge population.
